## Create the hero section

I want to create a new hero section for a gaming website. I have already moved a 3D GLB file into the current project folder. Go ahead and use that GLB file to integrate the 3D character into the hero section.

Here are the requirements based on the attached video: 3D character animation. Animate the character so it moves naturally with looping, spots walking normally and slowly, just like the character in the video. Replace the scroll-based animation where the camera moves around the character as the user scrolls. However, in the initial shot of the video, the camera starts very close to the character's face. I don't want my website to start from that scene. Please keep some distance between the camera and the character at the beginning.

Review the video and apply the exact same animation and interactions. Please focus only on creating this hero section.

## Improve the walking animation and adjust the scene

I loved everything, but the only issue is the walking animation for the 3D character. It looks really lame, especially his legs and walking, which are not really good. It looks like the character has a problem with walking. So go ahead and fix his legs and walking to make it more natural and add some aura to the character.

I want the main headline to appear in the background behind the 3D character, so it doesn't overlay him. I also want the scene to start on a closer shot of the character, like the reference video I attached, not quite that close, but closer than the current version.

## Add the remaining sections and the 3D card gallery

Next, I want to add three more sections to this website, in addition to a footer at the end. Go ahead and create these sections, and make sure the design and overall look align with the current hero section. I also want to create a special service section. This service section should include a scroll-driven 3D spiral gallery with project cards orbiting a central vertical sword. As the user scrolls, the cards rotate around the sword with something like a 3D element at the center, and descend along a curved scroll path in perspective. I have attached a screen record of the exact services section and this scroll-driven 3D effect. Please focus particularly on this section.

Include 14 cards in total, for three random cards, use Hexfield MCP to create three videos. You can also use Hexfield MCP to generate background images for these cards. All cards should have the glassy effect shown in the video, and the hover effect should match it exactly. Use Sedans 2.5 and GPT Image 2.5 to generate the images and videos. Ensure the images and videos align with the current project, which is a gaming website, feature a consistent character across the videos and images, along with similar characters and environments. Videos should be short looping videos, around three to five seconds long.
